Tableaux and Eulerian properties of the symmetric group

Alain Lascoux

Institut Gaspard Monge, Université Paris-Est
Alain.Lascoux@univ-mlv.fr
phalanstere.univ-mlv.fr/~al
Ehresmann defined an order (called Bruhat order) on the symmetric group, which plays a fundamental role in geometry, algebra and representation theory: two permutations are consecutive if they have consecutive length and differ by multiplication by a transposition (on the right or left).

thick arrows = permutohedron
The **EB-order** possesses many symmetry properties. For example, in every interval, there are as many permutations of even length than of odd length.

This type of properties is accounted by the notion of **Eulerian structure** : given a graded poset $X$, its incidence matrix $E$ (i.e. $E[x, y] = 1 \iff x \leq y$) is graded.

\[
E = E_0 + E_1 + E_2 + \ldots
\]

The poset is **Eulerian** if $E^{-1} = E_0 - E_1 + E_2 - E_3 + \ldots$.

The same notion applies to a **directed graph with a rank**.
Young tableaux may be viewed as chains of permutations w.r. to the EB-order.

\[
\begin{array}{cccc}
2 & 2 & 1 & 1 \\
4 & 3 & 3 & 2 \\
3 & 4 & 4 & 4 \\
1 & 1 & 2 & 3 \\
\end{array}
\leftrightarrow
\begin{array}{cccc}
1 & 3 & 4 & 2 \\
1 & 4 & 3 & 2 \\
2 & 4 & 3 & 1 \\
3 & 4 & 2 & 1 \\
\end{array}
\]

tableau chain

first permutation= left key = 1342 ,
last permutation=right key=3421

But keys may be obtained by the \textit{jeu de taquin} . . .
Keys by *jeu de taquin* on consecutive columns:

\[
\begin{array}{cccc}
5 & 6 & 1 & 3 \\
1 & 3 & 2 & 4 \\
\end{array}
\rightarrow
\begin{array}{cccc}
5 & 1 & 3 & 6 \\
1 & 3 & 2 & 4 \\
\end{array}
\rightarrow
\begin{array}{cccc}
5 & 1 & 3 & 6 \\
1 & 5 & 6 & 2 \\
\end{array}
\rightarrow
\begin{array}{cccc}
5 & 3 & 6 & 1 \\
1 & 2 & 6 & 4 \\
\end{array}
\rightarrow
\begin{array}{cccc}
1 & 5 & 3 & 6 \\
1 & 2 & 6 & 4 \\
\end{array}
\rightarrow
\begin{array}{cccc}
1 & 5 & 3 & 6 \\
6 & 4 & 6 & 2 \\
\end{array}
\]

= left key

rightkey =

= Alain Lascoux
Tableauhedron

5 / 28
Instead of permutations, one records also shapes, and one can use one of the following equivalent ways of denoting the same object:

key = **set of columns embedded into each other**
⇔ **tableau congruent to some word of type** \( \ldots 3^{v_3} 2^{v_2} 1^{v_1} \)
⇔ **monomial** \( x^v = x_1^{v_1} x_2^{v_2} \ldots \)
⇔ **weight** \( v = [v_1, v_2, \ldots] \).

For the above example, the right key is

\[
C(t) = \left\{ \begin{array}{ccc}
4 & 6 & 6 \\
4 & 4 & 2 \\
\end{array} \right\} \iff \begin{array}{ccc}
6 & 4 & 6 \\
2 & 4 & 4 \\
\end{array} \iff \begin{array}{ccc}
6 & 6 \\
4 & 4 & 4 \\
2 \\
\end{array}
\iff x_2 x_4^3 x_6^2 \iff [0, 1, 0, 3, 0, 2] \]
Keys are very useful to describe **Demazure characters**, but they can also be used for other problems in the theory of tableaux. For example, the shape of a product $t_1 t_2$ of two tableaux is equal to the sum of the shapes of $t_1$ and $t_2$ if and only if

$$\text{right key}(t_1) \leq \text{left key}(t_2) \quad (\text{componentwise})$$

Thus, the square of a tableau has twice the shape of the tableau iff the tableau is a key. The square of the preceding tableau, which is not a key, is

\[
\begin{array}{ccc}
5 & 3 & 6 \\
6 & 1 & 2 \\
4 & 3 & 6 \\
1 & 2 & 4
\end{array}
\quad \begin{array}{ccc}
5 & 3 & 6 \\
6 & 1 & 2 \\
4 & 3 & 6 \\
1 & 2 & 4
\end{array} = \begin{array}{ccc}
5 & 6 \\
3 & 4 \\
2 & 3 & 5 \\
1 & 1 & 2 & 4 & 6
\end{array}
\]

whose shape is $[2, 2, 3, 5] \neq 2 \times [1, 2, 3]$
Taquin is not enough
Crystal graphs are needed
Crystal graphs decompose the set of tableaux of the same shape into $i$-strings:
Example of a 3-string (one pairing 43)

\[
\begin{array}{c}
3 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 3 & 3 \\
\end{array}
\rightarrow
\begin{array}{c}
3 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 3 & 4 \\
\end{array}
\rightarrow
\begin{array}{c}
3 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 4 & 4 \\
\end{array}
\rightarrow
\begin{array}{c}
4 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 4 & 4 \\
\end{array}
\]

In fact, after paring and eliminating the letters $\neq 3, 4$, a 3-string reduces to

\[
333 \rightarrow 334 \rightarrow 344 \rightarrow 444
\]

Action of $s_i$ = symmetry with respect to the middle of the $i$-string
Action of $\pi_i$ on the head of the string = sum of all the elements of the string
One can also use $\hat{\pi}_i = \pi_i - 1 = \pi_i$ - identity. It sends the head of a $i$-string to the sum of all the other elements of the string.

\[
\begin{array}{c}
3 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 3 & 3
\end{array} = \begin{array}{c}
3 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 3 & 4
\end{array} + \begin{array}{c}
3 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 4 & 4
\end{array} + \begin{array}{c}
4 & 4 \\
2 & 2 & 3 \\
1 & 1 & 2 & 4 & 4
\end{array}
\]

These operators lift similar operators on $\mathcal{V}_0$:

$s_i$ transpose $x_i, x_{i+1}$, 
$\pi_i$ is the operator $f \rightarrow (x_i f - x_{i+1} f^{s_i}) (x_i - x_{i+1})^{-1}$
$\hat{\pi}_i = \pi_i - 1$ is the operator $f \rightarrow (f - f^{s_i}) (x_i/x_{i+1} - 1)^{-1}$
\[ \langle S_x = \Sigma t \rangle \quad \Longrightarrow \quad \langle \hat{K}_v \rangle \quad \Longleftarrow \quad \text{Free} \]

\[ \langle S_x \rangle = \text{Sym} \quad \Longrightarrow \quad \text{Schub} \quad \Longrightarrow \quad \text{Plax} \]

\[ \langle \wedge_x \rangle = \text{Sym} \quad \Longleftarrow \quad \langle \hat{K}_v \rangle \approx \text{Pol} \]
Tableaux generated by $\hat{\pi}_1$, $\hat{\pi}_2$, starting from a Yamanouchi tableau:

$\hat{K}_{210}^F = \begin{array}{c}
| \\
\end{array} \begin{array}{c}
2 \\
1 \\
1
\end{array}$

$\hat{K}_{120}^F = \begin{array}{c}
| \\
\end{array} \begin{array}{c}
2 \\
1 \\
2
\end{array}$

$\hat{K}_{102}^F = \begin{array}{c}
| \\
\end{array} \begin{array}{c}
2 \\
1 \\
3
\end{array} + \begin{array}{c}
| \\
\end{array} \begin{array}{c}
3 \\
1 \\
3
\end{array}$

$\hat{K}_{201}^F = \begin{array}{c}
| \\
\end{array} \begin{array}{c}
3 \\
1 \\
1
\end{array}$

$\hat{K}_{021}^F = \begin{array}{c}
| \\
\end{array} \begin{array}{c}
3 \\
1 \\
2
\end{array} + \begin{array}{c}
| \\
\end{array} \begin{array}{c}
3 \\
2 \\
2
\end{array}$

$\hat{K}_{012}^F = \begin{array}{c}
| \\
\end{array} \begin{array}{c}
3 \\
2 \\
3
\end{array}$
Given a partition $\lambda$, one defines $K_{\lambda}^F = \hat{K}_{\lambda}^F = \ldots 2^\lambda 2^1 1^1$, and the other key polynomials by recursion. For $i$, $\nu$ such that $\nu_i > \nu_{i+1}$, then

$$ K_{\nu S_i} = K_{\nu}^F \pi_i \quad \& \quad \hat{K}_{\nu S_i} = \hat{K}_{\nu}^F \pi_i $$

**Facts.** $\hat{K}_\nu^F$ is the sum of all tableaux with right key $\nu$.

$$ K_{\nu}^F = \sum_{u \leq \nu} \hat{K}_u^F $$

The tableaux in $K_{\nu}^F$ index a basis of a Demazure module.
The construction of the bases of Demazure modules is not symmetrical in the left and right keys. To recover symmetry, one defines operators on $\text{Free} \otimes \text{Free}$.

\[
\Psi_i = \hat{\pi}_i \otimes s_i + 1 \otimes \hat{\pi}_i \\
= \pi_i \otimes s_i + 1 \otimes \theta_i ,
\]

with $\theta_i = \hat{\pi}_i - s_i = \pi_i - 1 - s_i$.

Caution! These operators do not satisfy the braid relations.
Since one uses $1, \pi_i, \hat{\pi}_i$ on the left factor, this factor remains in the linear span of the $K_v^F$. One can project this factor on $\mathcal{Pol}$ without loss of information.

On the right factor, one uses also the $s_i$, which preserve tableaux, but not the linear span of the $K_v^F$. Thus, one takes $V_{\lambda}$, the linear span of all tableaux of shape $\lambda$ as second space.

**Proposition.** *Given a strict partition $\lambda \in \mathbb{N}^n$, a reduced decomposition $s_i \ldots s_j$, and $v = s_i \ldots s_j$, then*

$$K_{\lambda}^F \otimes \hat{K}_{\lambda}^F \oplus u \ldots \oplus j = \sum_u \sum_t K_u^F \otimes t$$

*sum over all weights $u \in \mathbb{N}^n$ which are a permutation of $\lambda$, all tableaux $t$ which have left key $u$ and right key $v$.***
Proof. By induction on the length of the reduced decomposition. Adding one factor $\omega_j$ and looking at the action on $j$-strings, or heads of $j$-strings is easy, as well as the modification of the left key. Reasoning is reduced to words in the two letters $j, j + 1$.

Here is an example of a 2-string, writing the variable letters in color. The letter in red determines the left key among $K^F_{6402}, K^F_{6042}$.

\[
\begin{array}{cccccc}
4 & 4 & 2 & 2 & 3 & 4 \\
1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\quad \rightarrow \quad
\begin{array}{cccccc}
4 & 4 & 2 & 3 & 3 & 4 \\
1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\quad \rightarrow \quad
\begin{array}{cccccc}
4 & 4 & 3 & 3 & 3 & 4 \\
1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

$K^F_{6402} \rightarrow K^F_{6402} \rightarrow K^F_{6042}$
Considering the component on the right only, given a strict partition \( \lambda \) and a reduced decomposition \( s_i \ldots s_j \), one obtains the Tableauhedron with top \( \lambda s_i \ldots s_j \) by the expansion of \( (s_i+\theta_i+1) \ldots (s_j+\theta_j+1) \).

\[
\begin{align*}
420 & \quad \theta_1 \quad \theta_2 \\
240 & \quad \theta_1 \theta_2 \\
402 & \quad s_2 \\
204 & \quad s_1 \theta_2 \\
\end{align*}
\]

\[
\begin{align*}
& \quad s_1 s_2 = 204 \\
&\text{and } t s_1 \theta_2 = \begin{bmatrix} 2 & 3 \\ 1 & 1 & 1 & 3 \\ 3 & 3 \\ 1 & 1 & 3 & 3 \end{bmatrix} + \begin{bmatrix} 2 & 2 \\ 1 & 1 & 3 & 3 \\ 1 & 1 & 1 & 3 \\ 2 & 2 \end{bmatrix} + \begin{bmatrix} 2 & 2 \\ 1 & 1 & 1 & 3 \\ 2 & 2 \\ 1 & 1 & 2 & 3 \end{bmatrix} .
\end{align*}
\]
Eulerian property satisfied by the edge multiplicities:

\[ 2 \times 2 = 1 \times 3 + 1 \times 1 \]

But, stronger statement, keeping the *evaluation* of tableaux instead of only their number.
One projects \( \text{Free} \otimes \text{Free} \) onto \( \text{Pol}^{\bullet} \otimes \text{Pol} \) by sending \( i \otimes j \) onto \( x_i^{-1} \otimes x_j \).

Since the image of \( \pi_i \) under the inversion of variables \( \bullet \) is \( -\theta_i \), one has

\[
(f \circ \bullet \otimes g)\circ_i = -f\circ \bullet \otimes g^{s_i} + f \circ \bullet \otimes g_{\theta_i}.
\]

Thus the operators to use on \( \text{Pol} \otimes \text{Pol} \) are

\[
\tilde{\circ}_i = -\theta_i \otimes s_i + 1 \otimes s_i
\]

followed by the evaluation

\[
f \otimes g \rightarrow f(1/x_1, \ldots, 1/x_n) \otimes g(x_1, \ldots, x_n)
\]
Our starting point was $x^\lambda \otimes x^\lambda$. Its image under $\widetilde{\U}_i$ is

$$x^\lambda \otimes x^\lambda \widetilde{\U}_i = -x^\lambda \theta_i \otimes x^{\lambda s_i} + x^\lambda \otimes (x^\lambda \theta_i)$$

which evaluates to 0 (one has in fact computed the image of $x^{-\lambda}x^\lambda = 1$ under the operator $\hat{\pi}_i = \partial_i x_{i+1}$).

At the level of tableaux, writing $t_{41} = \begin{ytableau} 2 \\ 1 1 1 1 \end{ytableau}$, $t_{14} = \begin{ytableau} 2 \\ 1 2 2 2 \end{ytableau}$, one has

$$t_{41} \theta_1 = \begin{ytableau} 2 \\ 1 1 1 2 \end{ytableau} + \begin{ytableau} 2 \\ 1 1 2 2 \end{ytableau} = t + t'$$

and the relation is the symmetry property:

$$-\frac{t_{14}}{t} - \frac{t_{14}}{t'} + \frac{t}{t_{41}} + \frac{t'}{t_{41}}$$

evaluates to 0.
Similarly, the action of $\tilde{\mathcal{U}}_i \tilde{\mathcal{U}}_j$ on $x^\lambda \otimes x^\lambda$, corresponding to the figure

\[ \sum t_1 \quad \sum t_2 \quad \sum t_5 \quad \sum t_3 \quad \sum t_4 \]

gives the relation

\[ \sum \frac{t_3}{t_1} + \sum \frac{t_4}{t_2} - \sum \frac{T'}{t_5} - \sum \frac{t_5}{T} \sim 0. \]
I shall not draw a picture for length 3! In general, let \( \lambda \in \mathbb{N}^n \) be a strict partition, \( \mathcal{T}_{\lambda} \) be the set of tableaux in \( \{1, \ldots, n\} \), \( \{\sigma\} \) be the set of permutation of \( \lambda \).

Let \( E = E_0 + E_1 + E_2 + \ldots \) be the matrix, filtered by distance, with entries

\[
E[\sigma, \zeta] = \sum_t ev(t)
\]

sum over all tableaux in \( \mathcal{T}_{\lambda} \) with left key \( \sigma \), right key \( \zeta \).

In particular, \( E_0 \) is the diagonal matrix with \( ev(\sigma) \) on its diagonal.

**Theorem.** The inverse of \( E \) is

\[
E_0 - E_1 + E_2 - E_3 + \ldots
\]
For example, the matrix and its inverse corresponding to the keys \([4, 2, 0], [4, 0, 2], [2, 4, 0], [2, 0, 4]\) are

\[
\begin{bmatrix}
  x_2^2 x_1^4 & x_2 x_3 x_1^4 & x_2^3 x_1^3 & x_2 x_3^2 x_1^3 + x_2^2 x_1^3 x_3 \\
  \cdot & x_3^2 x_1^4 & \cdot & x_3^3 x_1^3 \\
  \cdot & \cdot & x_2^4 x_1^2 & x_2 x_3^3 x_1^2 + x_2^2 x_1^2 x_3^2 + x_2^3 x_1^2 x_3 \\
  \cdot & \cdot & \cdot & x_3^4 x_1^2
\end{bmatrix}
\]

\[
\begin{bmatrix}
  \frac{1}{x_2^2 x_1^4} & - \frac{1}{x_2 x_3 x_1^4} & - \frac{1}{x_2^3 x_1^3} & \frac{1}{x_2 x_3^2 x_1^3} + \frac{1}{x_2^2 x_1^3 x_3} \\
  \cdot & \frac{1}{x_3^2 x_1^4} & \cdot & - \frac{1}{x_3^3 x_1^3} \\
  \cdot & \cdot & \frac{1}{x_2^4 x_1^2} & - \frac{1}{x_2 x_3^3 x_1^2} - \frac{1}{x_2^2 x_1^2 x_3^2} - \frac{1}{x_2^3 x_1^2 x_3} \\
  \cdot & \cdot & \cdot & \frac{1}{x_3^4 x_1^2}
\end{bmatrix}
\]
In summary, the preceding construction allows to understand sequences $t_1, t_2, t_3, \ldots$ of tableaux such that

$$\text{right key}(t_i) \leq \text{left key}(t_{i+1})$$

(that we call chains of tableaux).

Back to Schubert calculus:

**Postulation of Schubert subvarieties of a flag manifold**

$= \text{dimension of the space of sections of the powers of a line bundle } L^\lambda$ over the Schubert variety $\mathcal{G}_\sigma$

$$\iff (1 - zx^\lambda)^{-1} \mathcal{O}_{\mathcal{G}_\sigma} \pi_\omega \bigg|_{x_i=1} = (1 - zx^\lambda)^{-1} \pi_{\sigma^{-1}} \bigg|_{x_i=1}$$
Combinatorially: enumerate chains of tableaux of shape $\lambda$, and count them.

In the case of Grassmannians, this problem was solved by Hodge (with the help of Littlewood for the determinantal formula giving the postulation number). One has to enumerate chains of partitions (with respect to inclusion of diagrams), or, equivalently plane partitions.

For the usual Plücker embedding, $\lambda = \rho = [n-1, \ldots, 1]$. In terms of Key polynomials, one takes a permutation $\nu$ of $\rho$ and one studies the function

$$1 + zK_\nu + z^2K_{2\nu} + z^3K_{3\nu} + \ldots \bigg|_{x_i=1}$$
General fact: for the Schubert variety corresponding to $\sigma$, one obtains a rational function with denominator $(1 - z)^{\ell(\sigma) + 1}$, and for numerator a positive polynomial $E_\sigma$, whose description remains to be written in terms of the tableauhedron.

For example, for $n = 4$, taking, up to inversion, all permutations which do not belong to a Young subgroup, one has the following $E_\sigma$:

$[3, 1, 4, 2] : 1 + 8z + 3z^2$
$[3, 4, 1, 2] : 1 + 25z + 44z^2 + 8z^3$
$[4, 1, 2, 3] : 1 + 10z + 5z^2$
$[4, 1, 3, 2] : 1 + 18z + 24z^2 + 3z^3$
$[4, 2, 1, 3] : 1 + 19z + 25z^2 + 3z^3$
$[4, 2, 3, 1] : 1 + 43z + 150z^2 + 81z^3 + 5z^4$
$[4, 3, 1, 2] : 1 + 38z + 120z^2 + 58z^3 + 3z^4$
$[4, 3, 2, 1] : 1 + 57z + 302z^2 + 302z^3 + 57z^4 + z^5$
There is a symmetry such that \((1 - zx^\rho)^{-1} \pi_\sigma\) and \((1 - zx^\rho)^{-1} \hat{\pi}_\sigma\) have numerators reversed of each other.

Let us compute, for \(n = 4\), \((1 - zx^{3210})^{-1} \hat{\pi}_3 \hat{\pi}_2 \hat{\pi}_1\). There are 8 keys and 6 tableaux which are not keys:

\[
t_1 = \begin{array}{ccc}
3 & 2 & 3 \\
1 & 1 & 2 \\
\end{array}, \quad t_2 = \begin{array}{ccc}
4 & 2 & 3 \\
1 & 1 & 1 \\
\end{array}, \\
t_3 = \begin{array}{ccc}
4 & 2 & 3 \\
1 & 1 & 2 \\
\end{array}, \quad t_4 = \begin{array}{ccc}
4 & 2 & 3 \\
1 & 2 & 2 \\
\end{array}, \quad t_5 = \begin{array}{ccc}
4 & 3 & 3 \\
1 & 1 & 2 \\
\end{array}, \quad t_6 = \begin{array}{ccc}
4 & 3 & 3 \\
1 & 2 & 2 \\
\end{array}
\]

The numerator is

\[
z(1 + zt_0 + z^2 t_0 t_0 + z^3 t_0 t_0 t_0 + \ldots) \hat{\pi}_3 \hat{\pi}_2 \hat{\pi}_1 (1 - z)^4 \bigg|_{t_i=1}
\]

Explicitly, specializing the keys to 1, this numerator is

\[
z(1 + t_3 + t_4 + t_5 + t_6) + z^2(4 + t_1 + t_2 - t_3 + t_4 + t_5 + t_6 + t_2 t_5 + t_2 t_6) + z^3
\]

which specializes to 5z + 10z^2 + z^3, but Euler is needed to eliminate the minus sign!
Here is the structure with which to make the preceding computation, with the Euler relation \(2t_3 \sim t_2 t_5 + t_2 t_6\).
